

A digital twin is a synchronised virtual model of a physical system, kept current by a stream of measurements from that system and used to reason about states the physical system has not yet reached. The value of such a model rises with the fidelity of its synchronisation and with the breadth of the questions an operator can pose against it cheaply.

This control fixture contains only ordinary prose in a single column. It carries no running head, no footer page number, no figure labels, and no tabular material, so every structural stripper in the pipeline should leave it essentially untouched. Its recovery ratio is therefore the cleanest signal in the corpus for spotting an accidental regression.

Because the text reads as continuous sentences with terminal punctuation, no run of short unpunctuated lines exists for a figure heuristic to catch, and no digit-only line exists for a page-number rule to strip. A change that alters this fixture's numbers points at a bug in general prose handling rather than in any of the targeted structural special cases.
